Project -1.

Project Plan:

- ① Proposed functionality of application program?
→ The database application is/will be created by using real-world dataset acquired from Data.CMS.gov for Medicare Domain.

The dataset is a csv file that presents Doctors and Clinicians national downloadable file which are basically structured for unique identification at the clinician/enrolled record/group/address/medicare practise/medicare assignment level.

The main functionality of the application is to read & understand the dataset and give useful information for all users of different levels like the Patients, individual, Stakeholders, clinician about the performance of group of clinicians in various MIPS and also reflect the patient experience, behavior, feedback at different address contributing to enhancing the care quality.

- ③ Data You want to store in database.

→ I want to create 6 tables, one for each entity and store all the relevant information from the dataset to the columns of the tables (entity) that are drawn in ER-diagram.

③ Question- 4 bulleted question.

→ 4 Bulleted question as a data analyst I want to ask my database application user.

① How is patient experience scores (CAHPS) vary over different groups and what are the factors that influences that?

② What are the factors that most significantly predict a clinician's overall MPH score?

③ How do clinician's performance increase or decrease in many groups?

④ What are most frequently performed procedures by clinicians, and how does utilization vary across different location?

ER DIAGRAM.

Domain - MEDICARE

DataSet - data.cms.gov (<https://data.cms.gov>).
